4th Edition February 2018
Canine Leishmania infections are due to a widely distributed species, *Leishmania infantum*. However, in the new world and in the old world, other zoonotic species of *Leishmania* may infect dogs.

*Leishmania infantum* infection is typically transmitted by a specific group of phlebotomine vectors (sand flies) which represent the main risk of transmission.

However, non-vectorial modalities have also been demonstrated (venereal, vertical, dog to dog, blood transfusion.)
Table 1. Clinical manifestations and laboratory abnormalities found in CanL due to *L. infantum*.

**General**
- Generalized lymphadenomegaly
- Loss of body weight
- Decreased or increased appetite
- Lethargy
- Mucous membranes pallor
- Polyuria and polydipsia
- Fever
- Vomiting
- Diarrhea

**Cutaneous**
- Non-pruritic exfoliative dermatitis with or without alopecia
- Erosive-ulcerative dermatitis
- Nodular dermatitis
- Papular dermatitis
- Pustular dermatitis
- Onychogryphosis

**Ocular**
- Blepharitis (exfoliative, ulcerative or nodular) and conjunctivitis (nodular)
- Keratoconjunctivitis, either common or sicca
- Anterior uveitis
- Endophthalmitis

**Other**
- Mucocutaneous and mucosal ulcerative or nodular lesions (oral, genital and nasal)
- Epistaxis
- Lameness (erosive or non-erosive polyarthritis, osteomyelitis and polymyositis)
- Atrophic masticatory myositis
- Vascular disorders (systemic vasculitis and arterial thromboembolism)
- Neurological disorders

**Laboratory Abnormalities**

**CBC*/Hemostasis**
- Mild to moderate non-regenerative anemia
- Leukocytosis or leukopenia: lymphopenia, neutrophilia, neutropenia
- Thrombocytopenia
- Impaired secondary hemostasis and fibrinolysis

**Serum biochemical profile with proteins electrophoresis**
- Hyperproteinemia
- Hyperglobulinemia (polyclonal beta and/or gammaglobulinemia)
- Hypoalbuminemia
- Decreased albumin/globulin ratio
- Renal azotemia
- Elevated liver enzyme activities
- Proteinuria

* CBC: complete blood count
**DIAGNOSIS**

Diagnosis is based on clinical signs and/or clinicopathological abnormalities compatible with disease and by confirmation of *Leishmania infantum* infection, using mainly serological and molecular techniques.

**Main purposes for the diagnosis of *L. infantum* infection:**

A. Confirm the disease in a dog with clinical signs and/or clinicopathological abnormalities consistent with CanL (Table 1 and Figure 1).

B. Screening clinically healthy dogs living in or travelling to or from endemic areas:
   - blood donors
   - breeding dogs
   - dogs prior to leishmaniosis vaccination
   - imported dogs

**DIAGNOSTIC APPROACH**

Figure 1. Flow chart for the diagnostic approach to dogs not vaccinated against canine leishmaniosis (CanL) with suspected clinical signs and/or clinicopathological abnormalities consistent with CanL.

Dog with clinical signs and/or clinicopathological abnormalities consistent with CanL (in non-vaccinated)

- **POSITIVE**
  - Quantitative serology*
  - **NEGATIVE**
    - Cytological/histological evaluation
    - **NEGATIVE**
      - PCR
      - **NEGATIVE**
        - Consider other diagnoses
    - **POSITIVE**
      - Leishmania amastigotes
      - **NEGATIVE**
        - High suspicion of CanL
      - **YES**
        - Cytological/histological evaluation
      - **HIGH**
        - Quantitative serology*
      - **LOW**
        - Cytological/histological evaluation

* Cytology could be performed at the same time in any lesional tissue or biological fluid.

---

**Infected but healthy versus sick dogs**

- Dogs with clinical leishmaniosis are those presenting compatible clinical signs and/or clinicopathological abnormalities, and having a confirmed *L. infantum* infection.
- Dogs with subclinical infection (infected but clinically healthy) are those that present neither clinical signs on physical examination nor clinicopathological abnormalities on routine laboratory tests (CBC, biochemical profile and urinalysis) but have a confirmed *L. infantum* infection.

**Diagnostic methods**

- Parasitological: cytology/histology, immunohistochemistry and culture.
- Molecular: conventional, nested and real-time polymerase chain reaction (PCR).
- Serological: quantitative (IFAT and ELISA) and qualitative (rapid tests).

**What samples and techniques should be used for PCR?**

- First choice samples: bone marrow, lymph node, spleen, skin and conjunctival swabs.
  Less sensitive samples: blood, buffy coat and urine.
- Most sensitive technique: real-time PCR.

* *Leishmania infantum* amastigotes in a canine macrophage (© Torsten Naucke)
# Clinical Staging, Treatment and Prognosis

A system that classifies the disease into four stages with the goal of assisting the clinician in determining the appropriate therapy, forecasting prognosis, and implementing follow-up steps required for the management of the leishmaniosis patient.

**Table 2.** Clinical staging of CanL based on serological status, clinical signs, laboratory findings and type of therapy and prognosis for each clinical stage.

*Dogs with negative to medium positive antibody levels should be confirmed as infected with other diagnostic techniques such as cytology, histology/immunohistochemistry and PCR. High levels of antibodies are conclusive of a diagnosis of CanL and are defined as 3-4 fold increased of a well established laboratory reference cut-off.

**Dogs in Stage I (mild disease) are likely to require less prolonged treatment with one or two combined drugs (allopurinol, domperidone, meglumine antimoniate or miltefosine) or alternatively monitoring with no treatment. There is limited information on dogs in this stage and, therefore, treatment options remain to be defined.

**THERAPY**

### Table 3. Current treatment protocols for CanL.

<table>
<thead>
<tr>
<th>Drugs</th>
<th>Dose</th>
<th>Main side effects</th>
</tr>
</thead>
</table>
| Meglumine antimoniate a | 100 mg/kg SC, SID or divided in two doses, for 4-6 weeks (initial reduced dosages for 2-3 days may be useful to detect any adverse events) b | ☐ Potential nephrotoxicity  
☐ Pain and inflammation at injection site |
| Miltefosine a       | 2 mg/kg PO, once a day for 28 days        | ☐ Vomiting  
☐ Diarrhea                              |
| Allopurinol         | 10 mg/kg PO, twice a day for at least 6-12 months | ☐ Xanthine urolithiasis                |
| Domperidone c       | 0,5 mg/kg PO, once a day for 1 month      | ☐ Galactorrhea                          |

PO: per os; SC: subcutaneous

- Registered for veterinary use in most European countries; both drugs are recommended in combination with allopurinol.
- There is a limited number of studies on optimal treatment regimen. Recommended dosages off-label but according to pharmacokinetic and clinical studies in dogs. Treatment prolongation by 2-3 weeks may be considered if patient improvement is insufficient.
- Only considered for Stage I.

**MONITORING**

### Table 4. Recommended monitoring during and after treatment of CanL.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Frequency</th>
</tr>
</thead>
</table>
| Clinical history and physical examination       | Sick treated dogs  
| CBC, biochemical profile ± serum electrophoresis | After the first month of treatment and then every 3-4 months during the first year.  
| Complete urinalysis ± UPC                       | Later on, every 6-12 months in dogs fully recovered clinically with treatment. |
| Quantitative serology*                          | Not before 6 months after initial treatment and every 6-12 months. |
| Real-time PCR (optional)                        | At the same time as serology.                 |

CBC: complete blood count; UPC: urinary protein:creatinine ratio.

* Some dogs have a significant decrease in antibody levels (i.e. more than three two-fold dilutions difference between monitoring samples) associated with clinical improvement within 6-12 months of therapy. A marked increase in antibody levels (i.e. more than three two-fold dilutions difference between monitoring samples) should be interpreted as a marker of disease relapse, especially in dogs following the discontinuation of treatment.

**Disclaimer:** Information given here on drugs and dosages are based on a consensus of clinical and scientific experience by the LeishVet members. These recommendations have been published in scientific peer-reviewed scientific journals. Veterinary practitioners are requested to check with product leaflets and product registrations in their related country prior to any product selection and initiation of treatment.
PREVENTION

Prevention should include the application of a long-acting topical insecticide throughout the period of sand fly activity. Additionally, vaccination should be considered as a multimodal approach*.

Long-acting topical insecticides applied to dogs living in or travelling to endemic areas should be maintained during the entire period risk of potential exposure to/or activity of sand flies:

A Spot on formulations
Treatment with permethrin spot-on formulations provides repellent (anti-feeding) activity against sand flies for 3-4 weeks. In the case of dogs travelling to endemic areas, the product should be applied at least 2 days before departure.

B Collars
Deltamethrin-impregnated collars prevent phlebotomine sand fly bites. The efficacy of this collar preventing Leishmania infection has been demonstrated in several field trials. The duration of efficacy of this collar is 5-6 months. Clinical field studies performed in endemic areas using a flumethrin-containing collar indicate a significant reduction in the incidence of *L. infantum* infection. The duration of efficacy of this collar is 8 months. Collars should be applied at least 1-2 weeks before travelling.

*Based on a risk-benefit assessment (or in endemic areas), a multimodal approach combining the use of repellents and vaccination should be considered for an optimal prevention against both infection and development of clinical disease. Repellents reduce the risk of infection but do not prevent the appearance of clinical signs once the dog has been infected. Vaccination reduces the risk of the progression of the disease and the probability of developing clinical signs but does not prevent infection.

It is recommended to use serology alone or the combination of serology with PCR for screening healthy dogs and to avoid screening clinically healthy dogs (not vaccinated) only by PCR.

Confirmed low seropositive dogs should be monitored with physical examinations, routine laboratory and serological tests on a regular basis every 3-6 months to assess the possible progression of infection towards disease.

Management of all dogs with no clinical signs and laboratory abnormalities

**VACCINES**

A vaccine based on purified excreted/secreted antigens of *L. infantum* has been licensed in Europe since 2011. This vaccine contains a saponin adjuvant. First vaccination consists of three injections, three weeks apart. Protection is obtained one month after the third injection. Booster injections are given annually.

During 2016, a new vaccine against CanL was licensed in Europe. This new vaccine contains the active substance “protein Q”, a recombinant protein made of five different antigens from *L. infantum*. Following the European public assessment report (EPAR), this vaccine does not contain an adjuvant. Primo-vaccination includes only a single injection. Booster injections are given annually.

Both vaccines available in Europe can only be injected to healthy seronegative dogs of six months of age or older. They do not prevent the infection but the progression of the disease and reduce the probability of developing clinical signs.

FELINE LEISHMANIOSIS
ETIOLOGY AND TRANSMISSION

Feline Leishmania infections have been observed all over the world and are caused by endemic species also infecting humans and other animals in those areas. Leishmania infantum is transmitted to cats by sand flies, as these have been shown to feed on cats and to be infected after feeding on naturally infected cats. To date, non-vectorial transmission has not been described in cats but blood transfusion may be a source of infection of cats similar to humans and dogs.

GEOGRAPHIC DISTRIBUTION AND RISK FACTORS

Most information regarding feline L. infantum infection has come from the cases reported within the Mediterranean basin.

The prevalence rate of L. infantum infection in cats, as evaluated in many studies (Table 7), is not negligible; however, it is commonly lower than the prevalence of canine infection.

Table 7. Prevalence of L. infantum in Mediterranean countries (diverse serological or blood PCR techniques) according to studies performed in cats (1982 – 2017).

*Cats rehomed from Spain

Considering that cats may be a source of infection for sand flies and that cats may suffer from chronic infection, LeishVet postulates that infected cats may represent an additional domestic reservoir for L. infantum.

Approximately 100 clinical cases were reported in Europe during the last 25 years (Italy, Spain, France, Portugal) with some cases diagnosed (Switzerland) in cats imported from endemic regions.

Host factors predisposing to susceptibility may exist, as roughly half of the reported clinical cases have been observed in cats that could have had an impaired immune system secondary to feline immunodeficiency virus (FIV) or feline leukemia virus (FeLV) infections, immune-suppressive therapies or debilitating concomitant diseases.

Geographic distribution of feline Leishmania spp. infection is summarized in Table 8.

Table 8. Leishmania spp. detected in cats and countries where infection and/or disease cases were reported (1982-2017).

Clinical feline leishmaniosis (FeL) remains rare, even in areas where the disease is common in dogs. It is postulated that cats are therefore more resistant than dogs to L. infantum infection, but it cannot be excluded that the disease is underdiagnosed because it is unknown to most practitioners and masked by concurrent diseases, and feline medicine is still underdeveloped in many areas as compared to canine medicine.
CLINICAL PRESENTATION

Feline leishmaniosis is a chronic disease with clinical signs and clinicopathological abnormalities similar to those found in dogs (Table 9).

The most common muco-cutaneous lesions described are ulcerative and nodular dermatitis mostly distributed on the head or symmetrically on distal limbs (Figures 3 and 4). Uveitis is the most important ocular lesion (Figure 5). Oral lesions consist of nodules (tongue and/or gingival mucosa) or chronic stomatitis (Figure 6).

Complete blood count, biochemical profile and urinalysis are required in any suspected case to identify hyperglobulinemia, non-regenerative anemia, renal disease or other less common laboratory abnormalities associated with leishmaniosis.

FIV and FeLV testing are recommended in case of risk of exposure, as well as investigation of other concurrent diseases that alter feline immunocompetence.

There are no published controlled studies of FeL therapy.

In the absence of evidence indicating otherwise, empirical treatment giving the same drugs recommended for dogs is usually considered effective and apparently safe. **Allopurinol** (10 mg/kg 12 h or 20 mg/kg 24 h P.O., for at least 6 months) has been more frequently used than meglumine antimoniate (20-50 mg/kg 24 h S.C., for 30 days). These two drugs have also been given in combination.

Cats under therapy with allopurinol or meglumine antimoniate should be carefully monitored for any adverse effects.

---

**Disclaimer:** Information given here on drugs and dosages are based on a consensus of clinical and scientific experience by the LeishVet members. These recommendations have been published in scientific peer-reviewed scientific journals. Veterinary practitioners are requested to check with product leaflets and product registrations in their related country prior to any product selection and initiation of treatment.

DAT: direct agglutination test; ELISA: enzyme-linked immunosorbent assay; IFAT: indirect fluorescence antibody test; IHC: immunohistochemistry; PCR: polymerase chain reaction.

---

To confirm diagnosis, a quantitative serological test or Western blot should be performed in sera from cats with clinical signs or clinicopathological abnormalities compatible with FeL. However, in case of negative or low-positive antibody titers, a parasitological technique should be used to identify infection (cytology, histology, PCR or culture), before discharging diagnosis.

Evaluation of **Leishmania**-specific serology and PCR techniques (blood, lymph nodes or conjunctival swabs) are recommended in the following special situations in endemic areas:

- Blood donors
- Cats requiring immunosuppressive therapies
- Before re-homing cats to non-endemic areas

---

**Figure 7:** Fine needle aspirate of a reactive lymph node: lymphoid hyperplasia and a macrophage with *L. infantum* amastigotes (red arrows). May-Grünwald-Giemsa stain, scale bar = 20 μm (© Maria Grazia Pennisi)
MONITORING AND PROGNOSIS

Recurrence of clinical signs may occur; careful monitoring after the end of anti-Leishmania treatment should include physical examination, CBC, biochemical profile, urinalysis and quantitative serology at the frequencies indicated below (Table 11).

The life expectancy of cats with FeL is usually good (years) unless concurrent conditions (neoplasia, FIV/FeLV infections) or complications (renal disease) occur.

Table 11. Follow-up regimen.

* CBC: complete blood count.
** UPC: urinary protein: creatinine ratio.

PREVENTION

It is advised to protect (in endemic areas):

- Individual cats from the risk of developing infection and clinical disease.
- Feline population to improve the control of *L. infantum* infection in the vector.
- General prevention of sand fly bites is based on the same procedures as for dogs.
- Topical insecticides
  - Insecticides currently available for cats have no demonstrated effect in preventing the bites of sandflies.
- Most pyrethroids are toxic for cats. Flumethrin collar is at present the only pyrethroid formulation licensed for cats and it was able to reduce the incidence of *L. infantum* in cats in a field study.
- Test blood donors by antibody detection and blood PCR.
**KEY POINTS**

- *Leishmania infantum* is most likely transmitted to cats by sandflies although blood transfusion may be a non-vectorial route of transmission.
- The prevalence of *L. infantum* infection in cats is commonly lower than that of canine infection in endemic areas but often not negligible.
- Cats seem to be more resistant than dogs to *L. infantum* infection and subclinical feline infections are common in areas endemic for canine leishmaniosis while clinical illness in cats is rare.
- Skin lesions, lymph node enlargement and hypergammaglobulinemia are the most common clinical findings, followed by ocular and oral lesions, proteinuria, non-regenerative anemia.
- Infected cats may represent an additional domestic reservoir for *L. infantum* infection.
- Diagnosis is based on serological and parasitological techniques.
- Currently, treatment is empirically based on some drugs used also for dogs.
- Most pyrethroids are toxic for cats and only flumethrin collars are safe to be used.

**ABOUT THE LEISHVET GROUP**

*LeishVet* is a group of veterinary scientists from academic institutes in the Mediterranean basin and North America with a primary clinical and scientific interest in CanL. Its main goal is to improve the knowledge on different aspects of leishmaniosis in veterinary medicine and public health, including the development of consensus recommendations based on recent evidence-based literature and clinical experience that would represent the most current understanding of *Leishmania* infection in dogs, cats and other animals.
LEISHVET MEMBERS

Gad Baneth  Hebrew University of Jerusalem, Rehovot, Israel.
Patrick Bourdeau  Ecole Nationale Vétérinaire, Agroalimentaire et de l’Alimentation, Nantes-Atlantique (ONIRIS), Nantes, France.
Luís Cardoso  Universidade de Trás-os-Montes e Alto Douro, Vila Real, Portugal.
Lluis Ferrer  Universitat Autònoma de Barcelona, Bellaterra, Cerdanyola del Vallès (Barcelona), Spain.
Guadalupe Miró  Universidad Complutense de Madrid, Madrid, Spain.
Gaetano Oliva  Università di Napoli Federico II, Napoli, Italy.
Maria Grazia Pennisi  Università di Messina, Messina, Italy.
Christine Petersen  University of Iowa, College of Public Health, USA.
Laia Solano-Gallego  Universitat Autònoma de Barcelona, Bellaterra, Cerdanyola del Vallès (Barcelona), Spain.

LEISHVET HONORARY MEMBERS

Alek F. Koutinas  Aristotle University of Thessaloniki, Thessaloniki, Greece.
